# GENERATING AND DISPLAYING SPATIALLY OFFSET SUB-FRAMES ON A DIAMOND GRID

## **Cross-Reference to Related Applications**

5 This application is related to U.S. Patent Application Serial No. 10/213,555, filed on August 7, 2002, entitled IMAGE DISPLAY SYSTEM AND METHOD; U.S. Patent Application Serial No. 10/242,195, filed on September 11, 2002, entitled IMAGE DISPLAY SYSTEM AND METHOD; U.S. Patent Application Serial No. 10/242,545, filed on September 11, 2002, entitled IMAGE DISPLAY SYSTEM AND METHOD; U.S. Patent Application 10 Serial No. 10/631,681, filed July 31, 2003, entitled GENERATING AND DISPLAYING SPATIALLY OFFSET SUB-FRAMES; U.S. Patent Application Serial No. 10/632,042, filed July 31, 2003, entitled GENERATING AND DISPLAYING SPATIALLY OFFSET SUB-FRAMES; U.S. Patent Application Serial No. 10/672,845, filed September 26, 2003, entitled GENERATING AND 15 DISPLAYING SPATIALLY OFFSET SUB-FRAMES; U.S. Patent Application Serial No. 10/672,544, filed September 26, 2003, entitled GENERATING AND DISPLAYING SPATIALLY OFFSET SUB-FRAMES; U.S. Patent Application Serial No. \_\_\_\_\_, attorney docket number 200314885-1, filed on the 20 same date as the present application, and entitled GENERATING AND DISPLAYING SPATIALLY OFFSET SUB-FRAMES ON DIFFERENT TYPES OF GRIDS; and U.S. Patent Application Serial No. attorney docket number 10015701-1, filed on the same date as the present application, and entitled IMAGE DISPLAY SYSTEM AND METHOD. Each of the above U.S. Patent Applications is assigned to the assignee of the present 25 invention, and is hereby incorporated by reference herein.

### The Field of the Invention

The present invention generally relates to display systems, and more particularly to generating and displaying spatially offset sub-frames on a diamond grid.

### **Background of the Invention**

A conventional system or device for displaying an image, such as a display, projector, or other imaging system, produces a displayed image by addressing an array of individual picture elements or pixels arranged in a pattern, such as in horizontal rows and vertical columns, a diamond grid, or other pattern. A resolution of the displayed image for a pixel pattern with horizontal rows and vertical columns is defined as the number of horizontal rows and vertical columns of individual pixels forming the displayed image. The resolution of the displayed image is affected by a resolution of the display device itself as well as a resolution of the image data processed by the display device and used to produce the displayed image.

5

10

15

20

25

30

Typically, to increase a resolution of the displayed image, the resolution of the display device as well as the resolution of the image data used to produce the displayed image must be increased. Increasing a resolution of the display device, however, increases a cost and complexity of the display device. In addition, higher resolution image data may not be available or may be difficult to generate.

#### **Summary of the Invention**

One form of the present invention provides a method of displaying an image with a display device. The method includes receiving image data for the image on a diamond grid. The method includes generating a first sub-frame and a second sub-frame corresponding to the image data, the first and the second sub-frames each generated on a diamond grid. The method includes alternating between displaying the first sub-frame in a first position and displaying the second sub-frame in a second position spatially offset from the first position.

## **Description of the Preferred Embodiments**

In the following detailed description of the preferred embodiments, reference is made to the accompanying drawings, which form a part hereof, and in which is shown by way of illustration specific embodiments in which the invention may be practiced. It is to be understood that other embodiments may be utilized and structural or logical changes may be made without departing from the scope of the present invention. The following detailed description, therefore, is not to be taken in a limiting sense, and the scope of the present invention is defined by the appended claims.

## I. Spatial and Temporal Shifting of Sub-frames

Some display systems, such as some digital light projectors, may not have sufficient resolution to display some high resolution images. Such systems can be configured to give the appearance to the human eye of higher resolution images by displaying spatially and temporally shifted lower resolution images. The lower resolution images are referred to as sub-frames. A problem of sub-frame generation, which is addressed by embodiments of the present invention, is to determine appropriate values for the sub-frames so that the displayed sub-frames are close in appearance to how the high-resolution image from which the sub-frames were derived would appear if directly displayed.

One embodiment of a display system that provides the appearance of enhanced resolution through temporal and spatial shifting of sub-frames is described in the above-cited U.S. patent applications, and is summarized below with reference to Figures 1-4E.

Figure 1 is a block diagram illustrating an image display system 10 according to one embodiment of the present invention. Image display system 10 facilitates processing of an image 12 to create a displayed image 14. Image 12 is defined to include any pictorial, graphical, or textural characters, symbols, illustrations, or other representation of information. Image 12 is represented, for example, by image data 16. Image data 16 includes individual picture elements or pixels of image 12. While one image is illustrated and described as being

processed by image display system 10, it is understood that a plurality or series of images may be processed and displayed by image display system 10.

In one embodiment, image display system 10 includes a frame rate conversion unit 20 and an image frame buffer 22, an image processing unit 24, and a display device 26. As described below, frame rate conversion unit 20 and image frame buffer 22 receive and buffer image data 16 for image 12 to create an image frame 28 for image 12. Image processing unit 24 processes image frame 28 to define one or more image sub-frames 30 for image frame 28, and display device 26 temporally and spatially displays image sub-frames 30 to produce displayed image 14.

5

10

15

20

25

30

Image display system 10, including frame rate conversion unit 20 and image processing unit 24, includes hardware, software, firmware, or a combination of these. In one embodiment, one or more components of image display system 10, including frame rate conversion unit 20 and image processing unit 24, are included in a computer, computer server, or other microprocessor-based system capable of performing a sequence of logic operations. In addition, processing can be distributed throughout the system with individual portions being implemented in separate system components.

Image data 16 may include digital image data 161 or analog image data 162. To process analog image data 162, image display system 10 includes an analog-to-digital (A/D) converter 32. As such, A/D converter 32 converts analog image data 162 to digital form for subsequent processing. Thus, image display system 10 may receive and process digital image data 161 or analog image data 162 for image 12.

Frame rate conversion unit 20 receives image data 16 for image 12 and buffers or stores image data 16 in image frame buffer 22. More specifically, frame rate conversion unit 20 receives image data 16 representing individual lines or fields of image 12 and buffers image data 16 in image frame buffer 22 to create image frame 28 for image 12. Image frame buffer 22 buffers image data 16 by receiving and storing all of the image data for image frame 28, and frame rate conversion unit 20 creates image frame 28 by subsequently retrieving or extracting all of the image data for image frame buffer 22.

As such, image frame 28 is defined to include a plurality of individual lines or fields of image data 16 representing an entirety of image 12. In one embodiment, image frame 28 includes a plurality of columns and a plurality of rows of individual pixels on a rectangular grid representing image 12. In another embodiment, image frame 28 includes a plurality of pixels on a diamond grid representing image 12.

5

10

15

20

25

30

Frame rate conversion unit 20 and image frame buffer 22 can receive and process image data 16 as progressive image data or interlaced image data. With progressive image data, frame rate conversion unit 20 and image frame buffer 22 receive and store sequential fields of image data 16 for image 12. Thus, frame rate conversion unit 20 creates image frame 28 by retrieving the sequential fields of image data 16 for image 12. With interlaced image data, frame rate conversion unit 20 and image frame buffer 22 receive and store odd fields and even fields of image data 16 for image 12. For example, all of the odd fields of image data 16 are received and stored and all of the even fields of image data 16 are received and stored. As such, frame rate conversion unit 20 de-interlaces image data 16 and creates image frame 28 by retrieving the odd and even fields of image data 16 for image 12.

Image frame buffer 22 includes memory for storing image data 16 for one or more image frames 28 of respective images 12. Thus, image frame buffer 22 constitutes a database of one or more image frames 28. Examples of image frame buffer 22 include non-volatile memory (e.g., a hard disk drive or other persistent storage device) and may include volatile memory (e.g., random access memory (RAM)).

By receiving image data 16 at frame rate conversion unit 20 and buffering image data 16 with image frame buffer 22, input timing of image data 16 can be decoupled from a timing requirement of display device 26. More specifically, since image data 16 for image frame 28 is received and stored by image frame buffer 22, image data 16 can be received as input at any rate. As such, the frame rate of image frame 28 can be converted to the timing requirement of display device 26. Thus, image data 16 for image frame 28 can be extracted from image frame buffer 22 at a frame rate of display device 26.

In one embodiment, image processing unit 24 includes a resolution adjustment unit 34 and a sub-frame generation unit 36. As described below, resolution adjustment unit 34 receives image data 16 for image frame 28 and adjusts a resolution of image data 16 for display on display device 26, and sub-frame generation unit 36 generates a plurality of image sub-frames 30 for image frame 28. More specifically, image processing unit 24 receives image data 16 for image frame 28 at an original resolution and processes image data 16 to increase, decrease, or leave unaltered the resolution of image data 16. Accordingly, with image processing unit 24, image display system 10 can receive and display image data 16 of varying resolutions.

5

10

15

20

25

30

Sub-frame generation unit 36 receives and processes image data 16 for image frame 28 to define a plurality of image sub-frames 30 for image frame 28. If resolution adjustment unit 34 has adjusted the resolution of image data 16, sub-frame generation unit 36 receives image data 16 at the adjusted resolution. The adjusted resolution of image data 16 may be increased, decreased, or the same as the original resolution of image data 16 for image frame 28. Sub-frame generation unit 36 generates image sub-frames 30 with a resolution which matches the resolution of display device 26. Image sub-frames 30 are each of an area equal to image frame 28. In one embodiment, sub-frames 30 each include a plurality of columns and a plurality of rows of individual pixels on a rectangular grid representing a subset of image data 16 of image 12. In another embodiment, sub-frames 30 each include a plurality of pixels arranged on a diamond grid.

Image sub-frames 30 are spatially offset from each other when displayed. In one embodiment, image sub-frames 30 are offset from each other by a vertical distance and a horizontal distance, as described below.

Display device 26 receives image sub-frames 30 from image processing unit 24 and sequentially displays image sub-frames 30 to create displayed image 14. More specifically, as image sub-frames 30 are spatially offset from each other, display device 26 displays image sub-frames 30 in different positions according to the spatial offset of image sub-frames 30, as described below. As such, display device 26 alternates between displaying image sub-frames 30 for

image frame 28 to create displayed image 14. Accordingly, display device 26 displays an entire sub-frame 30 for image frame 28 at one time.

In one embodiment, display device 26 performs one cycle of displaying image sub-frames 30 for each image frame 28. Display device 26 displays image sub-frames 30 so as to be spatially and temporally offset from each other. In one embodiment, display device 26 optically steers image sub-frames 30 to create displayed image 14. As such, individual pixels of display device 26 are addressed to multiple locations.

5

10

15

20

25

30

In one embodiment, display device 26 includes an image shifter 38. Image shifter 38 spatially alters or offsets the position of image sub-frames 30 as displayed by display device 26. More specifically, image shifter 38 varies the position of display of image sub-frames 30, as described below, to produce displayed image 14.

In one embodiment, display device 26 includes a light modulator for modulation of incident light. The light modulator includes, for example, a plurality of micro-mirror devices arranged to form an array of micro-mirror devices. As such, each micro-mirror device constitutes one cell or pixel of display device 26. Display device 26 may form part of a display, projector, or other imaging system.

In one embodiment, image display system 10 includes a timing generator 40. Timing generator 40 communicates, for example, with frame rate conversion unit 20, image processing unit 24, including resolution adjustment unit 34 and sub-frame generation unit 36, and display device 26, including image shifter 38. As such, timing generator 40 synchronizes buffering and conversion of image data 16 to create image frame 28, processing of image frame 28 to adjust the resolution of image data 16 and generate image sub-frames 30, and positioning and displaying of image sub-frames 30 to produce displayed image 14. Accordingly, timing generator 40 controls timing of image display system 10 such that entire sub-frames of image 12 are temporally and spatially displayed by display device 26 as displayed image 14.

In one embodiment, as illustrated in Figures 2A and 2B, image processing unit 24 defines two image sub-frames 30 for image frame 28. More

specifically, image processing unit 24 defines a first sub-frame 301 and a second sub-frame 302 for image frame 28. As such, first sub-frame 301 and second sub-frame 302 each include a plurality of columns and a plurality of rows of individual pixels 18 of image data 16. Thus, first sub-frame 301 and second sub-frame 302 each constitute an image data array or pixel matrix of a subset of image data 16.

5

10

15

20

25

30

In one embodiment, as illustrated in Figure 2B, second sub-frame 302 is offset from first sub-frame 301 by a vertical distance 50 and a horizontal distance 52. As such, second sub-frame 302 is spatially offset from first sub-frame 301 by a predetermined distance. In one illustrative embodiment, vertical distance 50 and horizontal distance 52 are each approximately one-half of one pixel.

As illustrated in Figure 2C, display device 26 alternates between displaying first sub-frame 301 in a first position and displaying second sub-frame 302 in a second position spatially offset from the first position. More specifically, display device 26 shifts display of second sub-frame 302 relative to display of first sub-frame 301 by vertical distance 50 and horizontal distance 52. As such, pixels of first sub-frame 301 overlap pixels of second sub-frame 302. In one embodiment, display device 26 performs one cycle of displaying first sub-frame 301 in the first position and displaying second sub-frame 302 in the second position for image frame 28. Thus, second sub-frame 302 is spatially and temporally displayed relative to first sub-frame 301. The display of two temporally and spatially shifted sub-frames in this manner is referred to herein as two-position processing.

In another embodiment, as illustrated in Figures 3A-3D, image processing unit 24 defines four image sub-frames 30 for image frame 28. More specifically, image processing unit 24 defines a first sub-frame 301, a second sub-frame 302, a third sub-frame 303, and a fourth sub-frame 304 for image frame 28. As such, first sub-frame 301, second sub-frame 302, third sub-frame 303, and fourth sub-frame 304 each include a plurality of columns and a plurality of rows of individual pixels 18 of image data 16.

In one embodiment, as illustrated in Figures 3B-3D, second sub-frame 302 is offset from first sub-frame 301 by a vertical distance 50 and a horizontal distance 52, third sub-frame 303 is offset from first sub-frame 301 by a horizontal distance 54, and fourth sub-frame 304 is offset from first sub-frame 301 by a vertical distance 56. As such, second sub-frame 302, third sub-frame 303, and fourth sub-frame 304 are each spatially offset from each other and spatially offset from first sub-frame 301 by a predetermined distance. In one illustrative embodiment, vertical distance 50, horizontal distance 52, horizontal distance 54, and vertical distance 56 are each approximately one-half of one pixel.

5

10

15

20

25

30

As illustrated schematically in Figure 3E, display device 26 alternates between displaying first sub-frame 301 in a first position P<sub>1</sub>, displaying second sub-frame 302 in a second position P<sub>2</sub> spatially offset from the first position, displaying third sub-frame 303 in a third position P<sub>3</sub> spatially offset from the first position, and displaying fourth sub-frame 304 in a fourth position P<sub>4</sub> spatially offset from the first position. More specifically, display device 26 shifts display of second sub-frame 302, third sub-frame 303, and fourth sub-frame 304 relative to first sub-frame 301 by the respective predetermined distance. As such, pixels of first sub-frame 301, second sub-frame 302, third sub-frame 303, and fourth sub-frame 304 overlap each other.

In one embodiment, display device 26 performs one cycle of displaying first sub-frame 301 in the first position, displaying second sub-frame 302 in the second position, displaying third sub-frame 303 in the third position, and displaying fourth sub-frame 304 in the fourth position for image frame 28. Thus, second sub-frame 302, third sub-frame 303, and fourth sub-frame 304 are spatially and temporally displayed relative to each other and relative to first sub-frame 301. The display of four temporally and spatially shifted sub-frames in this manner is referred to herein as four-position processing.

Figures 4A-4E illustrate one embodiment of completing one cycle of displaying a pixel 181 from first sub-frame 301 in the first position, displaying a pixel 182 from second sub-frame 302 in the second position, displaying a pixel 183 from third sub-frame 303 in the third position, and displaying a pixel 184

from fourth sub-frame 304 in the fourth position. More specifically, Figure 4A illustrates display of pixel 181 from first sub-frame 301 in the first position, Figure 4B illustrates display of pixel 182 from second sub-frame 302 in the second position (with the first position being illustrated by dashed lines), Figure 4C illustrates display of pixel 183 from third sub-frame 303 in the third position (with the first position and the second position being illustrated by dashed lines), Figure 4D illustrates display of pixel 184 from fourth sub-frame 304 in the fourth position (with the first position, the second position, and the third position being illustrated by dashed lines), and Figure 4E illustrates display of pixel 181 from first sub-frame 301 in the first position (with the second position, the third position, and the fourth position being illustrated by dashed lines).

5

10

15

20

25

30

Sub-frame generation unit 36 (Figure 1) generates sub-frames 30 based on image data in image frame 28. It will be understood by a person of ordinary skill in the art that functions performed by sub-frame generation unit 36 may be implemented in hardware, software, firmware, or any combination thereof. The implementation may be via a microprocessor, programmable logic device, or state machine. Components of the present invention may reside in software on one or more computer-readable mediums. The term computer-readable medium as used herein is defined to include any kind of memory, volatile or non-volatile, such as floppy disks, hard disks, CD-ROMs, flash memory, read-only memory (ROM), and random access memory.

In one form of the invention, sub-frames 30 have a lower resolution than image frame 28. Thus, sub-frames 30 are also referred to herein as low resolution images 30, and image frame 28 is also referred to herein as a high resolution image 28. It will be understood by persons of ordinary skill in the art that the terms low resolution and high resolution are used herein in a comparative fashion, and are not limited to any particular minimum or maximum number of pixels. In one embodiment, sub-frame generation unit 36 is configured to generate sub-frames 30 based on one of five algorithms. These five algorithms are referred to herein as the following: (1) nearest neighbor; (2) bilinear; (3) spatial domain; (4) frequency domain; and (5) adaptive multi-pass.

The nearest neighbor algorithm and the bilinear algorithm according to one form of the invention generate sub-frames 30 by combining pixels from a high resolution image 28. The spatial domain algorithm and the frequency domain algorithm according to one form of the invention generate sub-frames 30 based on the minimization of a global error metric that represents a difference between a simulated high resolution image and a desired high resolution image 28. The adaptive multi-pass algorithm according to one form of the invention generates sub-frames 30 based on the minimization of a local error metric. In one embodiment, sub-frame generation unit 36 includes memory for storing a relationship between sub-frame values and high resolution image values, wherein the relationship is based on minimization of an error metric between the high resolution image values and a simulated high resolution image that is a function of the sub-frame values. Embodiments of each of these five algorithms are described below with reference to Figures 5-18.

15

20

25

30

10

## II. Nearest Neighbor

Figure 5 is a diagram illustrating the generation of low resolution sub-frames 30A and 30B from an original high resolution image 28 using a nearest neighbor algorithm according to one embodiment of the present invention. In the illustrated embodiment, high resolution image 28 includes four columns and four rows of pixels, for a total of sixteen pixels H1-H16. In one embodiment of the nearest neighbor algorithm, a first sub-frame 30A is generated by taking every other pixel in a first row of the high resolution image 28, skipping the second row of the high resolution image 28, taking every other pixel in the third row of the high resolution image 28, and repeating this process throughout the high resolution image 28. Thus, as shown in Figure 5, the first row of sub-frame 30A includes pixels H1 and H3, and the second row of sub-frame 30A includes pixels H9 and H11. In one form of the invention, a second sub-frame 30B is generated in the same manner as the first sub-frame 30A, but the process begins at a pixel H6 that is shifted down one row and over one column from the first pixel H1. Thus, as shown in Figure 5, the first row of sub-frame 30B includes

pixels H6 and H8, and the second row of sub-frame 30B includes pixels H14 and H16.

In one embodiment, the nearest neighbor algorithm is implemented with a 2x2 filter with three filter coefficients of "0" and a fourth filter coefficient of "1" to generate a weighted sum of the pixel values from the high resolution image. Displaying sub-frames 30A and 30B using two-position processing as described above gives the appearance of a higher resolution image. The nearest neighbor algorithm is also applicable to four-position processing, and is not limited to images having the number of pixels shown in Figure 5.

10

15

5

### III. Bilinear

Figure 6 is a diagram illustrating the generation of low resolution sub-frames 30C and 30D from an original high resolution image 28 using a bilinear algorithm according to one embodiment of the present invention. In the illustrated embodiment, high resolution image 28 includes four columns and four rows of pixels, for a total of sixteen pixels H1-H16. Sub-frame 30C includes two columns and two rows of pixels, for a total of four pixels L1-L4. And sub-frame 30D includes two columns and two rows of pixels, for a total of four pixels L5-L8.

In one embodiment, the values for pixels L1-L8 in sub-frames 30C and 30D are generated from the pixel values H1-H16 of image 28 based on the following Equations I-VIII:

### **Equation I**

$$L1 = (4H1 + 2H2 + 2H5) / 8$$

25 Equation II

$$L2 = (4H3 + 2H4 + 2H7) / 8$$

**Equation III** 

$$L3 = (4H9 + 2H10 + 2H13) / 8$$

Equation IV

30 
$$L4 = (4H11 + 2H12 + 2H15) / 8$$

Equation V

$$L5 = (4H6 + 2H2 + 2H5) / 8$$

Equation VI

L6 = (4H8 + 2H4 + 2H7) / 8

Equation VII

L7 = (4H14 + 2H10 + 2H13) / 8

5 Equation VIII

10

15

20

25

30

L8 = (4H16 + 2H12 + 2H15) / 8

As can be seen from the above Equations I-VIII, the values of the pixels L1-L4 in sub-frame 30C are influenced the most by the values of pixels H1, H3, H9, and H11, respectively, due to the multiplication by four. But the values for the pixels L1-L4 in sub-frame 30C are also influenced by the values of diagonal neighbors of pixels H1, H3, H9, and H11. Similarly, the values of the pixels L5-L8 in sub-frame 30D are influenced the most by the values of pixels H6, H8, H14, and H16, respectively, due to the multiplication by four. But the values for the pixels L5-L8 in sub-frame 30D are also influenced by the values of diagonal neighbors of pixels H6, H8, H14, and H16.

In one embodiment, the bilinear algorithm is implemented with a 2x2 filter with one filter coefficient of "0" and three filter coefficients having a non-zero value (e.g., 4, 2, and 2) to generate a weighted sum of the pixel values from the high resolution image. In another embodiment, other values are used for the filter coefficients. Displaying sub-frames 30C and 30D using two-position processing as described above gives the appearance of a higher resolution image. The bilinear algorithm is also applicable to four-position processing, and is not limited to images having the number of pixels shown in Figure 6.

In one form of the nearest neighbor and bilinear algorithms, sub-frames 30 are generated based on a linear combination of pixel values from an original high resolution image as described above. In another embodiment, sub-frames 30 are generated based on a non-linear combination of pixel values from an original high resolution image. For example, if the original high resolution image is gamma-corrected, appropriate non-linear combinations are used in one embodiment to undo the effect of the gamma curve.

## IV. Systems for Generating Simulated High Resolution Images

5

10

15

20

25

30

Figures 7-10 illustrate systems for generating simulated high resolution images. Based on these systems, spatial domain, frequency domain, and adaptive multi-pass algorithms for generating sub-frames are developed, as described in further detail below.

Figure 7 is a block diagram illustrating a system 400 for generating a simulated high resolution image 412 from two 4x4 pixel low resolution subframes 30E according to one embodiment of the present invention. System 400 includes upsampling stage 402, shifting stage 404, convolution stage 406, and summation stage 410. Sub-frames 30E are upsampled by upsampling stage 402 based on a sampling matrix, M, thereby generating upsampled images. The upsampled images are shifted by shifting stage 404 based on a spatial shifting matrix, S, thereby generating shifted upsampled images. The shifted upsampled images are convolved with an interpolating filter at convolution stage 406, thereby generating blocked images 408. In the illustrated embodiment, the interpolating filter is a 2x2 filter with filter coefficients of "1", and with the center of the convolution being the upper left position in the 2x2 matrix. The interpolating filter simulates the superposition of low resolution sub-frames on a high resolution grid. The low resolution sub-frame pixel data is expanded so that the sub-frames can be represented on a high resolution grid. The interpolating filter fills in the missing pixel data produced by upsampling. The blocked images 408 are weighted and summed by summation block 410 to generate the 8x8 pixel simulated high resolution image 412.

Figure 8 is a block diagram illustrating a system 500 for generating a simulated high resolution image 512 for two-position processing based on separable upsampling of two 4x4 pixel low resolution sub-frames 30F and 30G according to one embodiment of the present invention. System 500 includes upsampling stages 502 and 514, shifting stage 518, convolution stages 506 and 522, summation stage 508, and multiplication stage 510. Sub-frame 30F is upsampled by a factor of two by upsampling stage 502, thereby generating an 8x8 pixel upsampled image 504. The dark pixels in upsampled image 504 represent the sixteen pixels from sub-frame 30F, and the light pixels in

upsampled image 504 represent zero values. Sub-frame 30G is upsampled by a factor of two by upsampling stage 514, thereby generating an 8x8 pixel upsampled image 516. The dark pixels in upsampled image 516 represent the sixteen pixels from sub-frame 30G, and the light pixels in upsampled image 516 represent zero values. In one embodiment, upsampling stages 502 and 514 upsample sub-frames 30F and 30G, respectively, using a diagonal sampling matrix.

5

10

15

20

25

30

The upsampled image 516 is shifted by shifting stage 518 based on a spatial shifting matrix, S, thereby generating shifted upsampled image 520. In the illustrated embodiment, shifting stage 518 performs a one pixel diagonal shift. Images 504 and 520 are convolved with an interpolating filter at convolution stages 506 and 522, respectively, thereby generating blocked images. In the illustrated embodiment, the interpolating filter at convolution stages 506 and 522 is a 2x2 filter with filter coefficients of "1", and with the center of the convolution being the upper left position in the 2x2 matrix. The blocked images generated at convolution stages 506 and 522 are summed by summation block 508, and multiplied by a factor of 0.5 at multiplication stage 510, to generate the 8x8 pixel simulated high resolution image 512. The image data is multiplied by a factor of 0.5 at multiplication stage 510 because, in one embodiment, each of the sub-frames 30F and 30G is displayed for only half of the time slot per period allotted to a color. In another embodiment, rather than multiplying by a factor of 0.5 at multiplication stage 510, the filter coefficients of the interpolating filter at stages 506 and 522 are reduced by a factor of 0.5.

In one embodiment, as shown in Figure 8 and described above, the low resolution sub-frame data is represented by two separate sub-frames 30F and 30G, which are separately upsampled based on a diagonal sampling matrix (i.e., separable upsampling). In another embodiment, as described below with reference to Figure 9, the low resolution sub-frame data is represented by a single sub-frame, which is upsampled based on a non-diagonal sampling matrix (i.e., non-separable upsampling).

Figure 9 is a block diagram illustrating a system 600 for generating a simulated high resolution image 610 for two-position processing based on non-

separable upsampling of an 8x4 pixel low resolution sub-frame 30H according to one embodiment of the present invention. System 600 includes quincunx upsampling stage 602, convolution stage 606, and multiplication stage 608. Sub-frame 30H is upsampled by quincunx upsampling stage 602 based on a quincunx sampling matrix, **Q**, thereby generating upsampled image 604. The dark pixels in upsampled image 604 represent the thirty-two pixels from sub-frame 30H, and the light pixels in upsampled image 604 represent zero values. Sub-frame 30H includes pixel data for two 4x4 pixel sub-frames for two-position processing. The dark pixels in the first, third, fifth, and seventh rows of upsampled image 604 represent pixels for a first 4x4 pixel sub-frame, and the dark pixels in the second, fourth, sixth, and eighth rows of upsampled image 604 represent pixels for a second 4x4 pixel sub-frame.

5

10

15

20

25

30

The upsampled image 604 is convolved with an interpolating filter at convolution stage 606, thereby generating a blocked image. In the illustrated embodiment, the interpolating filter is a 2x2 filter with filter coefficients of "1", and with the center of the convolution being the upper left position in the 2x2 matrix. The blocked image generated by convolution stage 606 is multiplied by a factor of 0.5 at multiplication stage 608, to generate the 8x8 pixel simulated high resolution image 610.

Figure 10 is a block diagram illustrating a system 700 for generating a simulated high resolution image 706 for four-position processing based on subframe 30I according to one embodiment of the present invention. In the embodiment illustrated in Figure 10, sub-frame 30I is an 8x8 array of pixels. Sub-frame 30I includes pixel data for four 4x4 pixel sub-frames for four-position processing. Pixels A1-A16 represent pixels for a first 4x4 pixel sub-frame, pixels B1-B16 represent pixels for a second 4x4 pixel sub-frame, pixels C1-C16 represent pixels for a third 4x4 pixel sub-frame, and pixels D1-D16 represent pixels for a fourth 4x4 pixel sub-frame.

The sub-frame 30I is convolved with an interpolating filter at convolution stage 702, thereby generating a blocked image. In the illustrated embodiment, the interpolating filter is a 2x2 filter with filter coefficients of "1", and with the center of the convolution being the upper left position in the 2x2

matrix. The blocked image generated by convolution stage 702 is multiplied by a factor of 0.25 at multiplication stage 704, to generate the 8x8 pixel simulated high resolution image 706. The image data is multiplied by a factor of 0.25 at multiplication stage 704 because, in one embodiment, each of the four subframes represented by sub-frame 30I is displayed for only one fourth of the time slot per period allotted to a color. In another embodiment, rather than multiplying by a factor of 0.25 at multiplication stage 704, the filter coefficients of the interpolating filter are correspondingly reduced.

### 10 V. Generation of Sub-frames Based on Error Minimization

5

15

20

25

30

As described above, systems 400, 500, 600, and 700 generate simulated high resolution images 412, 512, 610, and 706, respectively, based on low resolution sub-frames. If the sub-frames are optimal, the simulated high resolution image will be as close as possible to the original high resolution image 28. Various error metrics may be used to determine how close a simulated high resolution image is to an original high resolution image, including mean square error, weighted mean square error, as well as others.

Figure 11 is a block diagram illustrating the comparison of a simulated high resolution image 412/512/610/706 and a desired high resolution image 28 according to one embodiment of the present invention. A simulated high resolution image 412, 512, 610, or 706, is subtracted on a pixel-by-pixel basis from high resolution image 28 at subtraction stage 802. In one embodiment, the resulting error image data is filtered by a human visual system (HVS) weighting filter (W) 804. In one form of the invention, HVS weighting filter 804 filters the error image data based on characteristics of the human visual system. In one embodiment, HVS weighting filter 804 reduces or eliminates low frequency errors. The mean squared error of the filtered data is then determined at stage 806 to provide a measure of how close the simulated high resolution image 412, 512, 610, or 706 is to the desired high resolution image 28.

In one embodiment, systems 400, 500, 600, and 700 are represented mathematically in an error cost equation that measures the difference between a simulated high resolution image 412, 512, 610, or 706, and the original high

resolution image 28. Optimal sub-frames are identified by solving the error cost equation for the sub-frame data that provides the minimum error between the simulated high resolution image and the desired high resolution image. In one embodiment, globally optimum solutions are obtained in the spatial domain and in the frequency domain, and a locally optimum solution is obtained using an adaptive multi-pass algorithm. The spatial domain, frequency domain, and adaptive multi-pass algorithms are described in further detail below with reference to Figures 12-18.

## 10 VI. Spatial Domain

5

20

25

A spatial domain solution for generating optimal sub-frames according to one embodiment is described in the context of the system 600 shown in Figure 9. The system 600 shown in Figure 9 can be represented mathematically in an error cost function by the following Equation IX:

## 15 <u>Equation IX</u>

$$l_{\mathcal{Q}}^* = \underset{l_{\mathcal{Q}}}{\operatorname{argmin}} \ J = \underset{l_{\mathcal{Q}}}{\operatorname{argmin}} \sum_{\mathbf{n}} \left( \sum_{\mathbf{k}} l_{\mathcal{Q}}(\mathbf{k}) f(\mathbf{n} - \mathbf{k}) - h(\mathbf{n}) \right)^2$$

where:

 $l_Q^* = \text{optimal low resolution data for sub-frame}$  30H;

J =error cost function to be minimized;

n and k = indices for identifying high resolution pixel locations for images 604 and 610;

 $l_Q(\mathbf{k})$  = image data from upsampled image 604 at location  $\mathbf{k}$ ;

 $f(\mathbf{n} - \mathbf{k})$  = filter coefficient of the interpolating filter at a position  $\mathbf{n} - \mathbf{k}$ ; and

 $h(\mathbf{n})$  = image data for desired high resolution image 28 at location  $\mathbf{n}$ .

The summation of " $l_Q(\mathbf{k}) f(\mathbf{n} - \mathbf{k})$ " in Equation IX represents the convolution of the upsampled image 604 and the interpolating filter, f, performed

at stage 606 in system 600. The filter operation is performed by essentially sliding the lower right pixel of the 2x2 interpolating filter over each pixel of the upsampled image 604. The four pixels of the upsampled image 604 within the 2x2 interpolating filter window are multiplied by the corresponding filter coefficient (i.e., "1" in the illustrated embodiment). The results of the four multiplications are summed, and the value for the pixel of the upsampled image 604 corresponding to the lower right position of the interpolating filter is replaced by the sum of the four multiplication results. The high resolution data,  $h(\mathbf{n})$ , from the high resolution image 28 is subtracted from the convolution value,  $l_Q(\mathbf{k}) f(\mathbf{n} - \mathbf{k})$ , to provide an error value. The summation of the squared error over all of the high resolution pixel locations provides a measure of the error to be minimized.

An optimal spatial domain solution can be obtained by taking the derivative of Equation IX with respect to each of the low resolution pixels, and setting it equal to zero as shown in the following Equation X:

#### Equation X

$$\frac{\partial J}{\partial l_Q^*(\mathbf{t})} = 0, \quad \mathbf{t} \in \Theta$$

where:

 $\Theta$  = the set of quincunx lattice points.

Thus, as can be seen from Equation X, the derivative is taken only at the set of quincunx lattice points, which correspond to the dark pixels in upsampled image 604 in Figure 9. Inserting the equation for J given in Equation IX into Equation X, and taking the derivative as specified in Equation X, results in the following Equation XI:

## **Equation XI**

$$\sum_{\mathbf{k}}l_{Q}^{*}(\mathbf{k})C_{ff}(\mathbf{t}-\mathbf{k})=\sum_{\mathbf{n}}h(\mathbf{n})f(\mathbf{n}-\mathbf{t}),\quad \mathbf{t}\in\Theta$$

25

20

5

10

15

The symbol,  $C_{ff}$ , in Equation XI represents the auto-correlation coefficients of the interpolating filter, f, as defined by the following Equation XII:

## **Equation XII**

$$C_{ff}(\mathbf{n}) = \sum_{\mathbf{k}} f(\mathbf{n}) f(\mathbf{n} + \mathbf{k})$$

Equation XII can be put into vector form as shown in the following Equation XIII:

## 5 Equation XIII

10

15

20

$$\mathbf{C}_{ff}\mathbf{l}_{O}^{*}=\mathbf{h}_{f}, \quad \mathbf{t}\in\Theta$$

where:

 $C_{ff}$  = matrix of auto-correlation coefficients of the interpolating filter, f.

 $l_Q^*$  = vector representing the unknown image data for sub-frame 30H, as well as "don't care" data (i.e., the image data corresponding to the light pixels in upsampled image 604);

 $\mathbf{h}_f$  = vector representing a filtered version of the simulated high resolution image 610 using the interpolating filter, f.

Deleting the rows and columns corresponding to "don't care" data (i.e., the data that is not in the set of quincunx lattice points,  $\Theta$ ), results in the following Equation XIV:

## **Equation XIV**

$$\widetilde{\mathbf{C}}_{ff}\widetilde{\mathbf{I}}_{Q}^{*} = \widetilde{\mathbf{h}}_{f}$$
 where:

 $\tilde{\mathbf{l}}_{Q}^{*}$  = vector representing only the unknown image data for sub - frame 30H.

The above Equation XIV is a sparse non-Toeplitz system representing a sparse system of linear equations. Since the matrix of auto-correlation

coefficients is known, and the vector representing the filtered version of the simulated high resolution image 610 is known, Equation XIV can be solved to determine the optimal image data for sub-frame 30H. In one embodiment, sub-frame generation unit 36 is configured to solve Equation XIV to generate sub-frames 30.

## VII. Frequency Domain

5

10

15

20

25

30

A frequency domain solution for generating optimal sub-frames 30 according to one embodiment is described in the context of the system 500 shown in Figure 8. Before describing the frequency domain solution, a few properties of the fast fourier transform (FFT) that are applicable to the frequency domain solution are described with reference to Figures 12 and 13.

Figure 12 is a diagram illustrating the effect in the frequency domain of the upsampling of a 4x4 pixel sub-frame 30J according to one embodiment of the present invention. As shown in Figure 12, sub-frame 30J is upsampled by a factor of two by upsampling stage 902 to generate an 8x8 pixel upsampled image 904. The dark pixels in upsampled image 904 represent the sixteen pixels from sub-frame 30J, and the light pixels in upsampled image 904 represent zero values. Taking the FFT of sub-frame 30J results in image (L) 906. Taking the FFT of upsampled image 904 results in image (L) 908 includes four 4x4 pixel portions, which are image portion (L) 910A, image portion (L) 910B, image portion (L) 910C, and image portion (L) 910D. As shown in Figure 12, image portions 910A-910D are each the same as image 906 (i.e., L<sub>1</sub> = L<sub>2</sub> = L<sub>3</sub> = L<sub>4</sub> = L).

Figure 13 is a diagram illustrating the effect in the frequency domain of the shifting of an 8x8 pixel upsampled sub-frame 904 according to one embodiment of the present invention. As shown in Figure 13, upsampled sub-frame 904 is shifted by shifting stage 1002 to generate shifted image 1004. Taking the FFT of upsampled sub-frame 904 results in image  $(L_U)$  1006. Taking the FFT of shifted image 1004 results in image  $(L_US)$  1008. Image  $(L_US)$  1008 includes four 4x4 pixel portions, which are image portion  $(LS_I)$  1010A, image portion  $(LS_I)$  1010B, image portion  $(LS_I)$  1010C, and image portion  $(LS_I)$ 

1010D. As shown in Figure 13, image 1008 is the same as image 1006 multiplied by a complex exponential, W, (i.e.,  $L_US = W \cdot L_U$ ), where " $\bullet$ " denotes pointwise multiplication. The values for the complex exponential, W, are given by the following Equation XV:

## 5 Equation XV

$$[W]_{(k_1,k_2)} = e^{\frac{-j2\pi(k_1+k_2)}{MN}}$$
 where:

 $k_1$  = row coordinate in the FFT domain;  $k_2$  = column coordinate in the FFT domain; M = number of columns in the image; and

N = number of rows in the image.

The system 500 shown in Figure 8 can be represented mathematically in an error cost function by the following Equation XVI:

## **Equation XVI**

where:

$$(\mathbf{L}_{A}^{*}, \mathbf{L}_{B}^{*}) = \underset{(\mathbf{L}_{A}, \mathbf{L}_{B})}{\operatorname{argmin}} J = \underset{(\mathbf{L}_{A}, \mathbf{L}_{B})}{\operatorname{argmin}} \sum_{i} [\widehat{\mathbf{F}}_{i} (\mathbf{L}_{A} + \widehat{\mathbf{W}}_{i} \mathbf{L}_{B}) - \mathbf{H}_{i}]^{H} [\widehat{\mathbf{F}}_{i} (\mathbf{L}_{A} + \widehat{\mathbf{W}}_{i} \mathbf{L}_{B}) - \mathbf{H}_{i}]$$

( $\mathbf{L}_{A}^{*}, \mathbf{L}_{B}^{*}$ ) = vectors representing the optimal FFT's of sub-frames 30F and 30G, respectively, shown in Figure 8; J = error cost function to be minimized;

i = index identifying FFT blocks that are averaged (e.g., for image 908 in Figure 12, four blocks are averaged, with i=1 corresponding to block 910A, i=2 corresponding to block 910B, i=3 corresponding to block 910C, and i=4 corresponding to block 910D);

 $\mathbf{F}$  = matrix representing the FFT of the interpolating filter, f;

 $L_A$  = vector representing the FFT of sub-frame 30F shown in Figure 8;

 $L_B$  = vector representing the FFT of sub-frame 30G shown in Figure 8;

20

10

W = matrix representing the FFT of the complex coefficient given by Equation XV;

**H** = vector representing the FFT of the desired high resolution image 28.

The superscript "H" in Equation XVI represents the Hermitian (i.e.,  $X^H$  is the Hermitian of X). The "hat" over the letters in Equation XVI indicates that those letters represent a diagonal matrix, as defined in the following Equation XVII:

## **Equation XVII**

$$\widehat{\mathbf{X}} = diag(\mathbf{X}) = \begin{pmatrix} X_1 & 0 & 0 & 0 \\ 0 & X_2 & 0 & 0 \\ 0 & 0 & X_3 & 0 \\ 0 & 0 & 0 & X_4 \end{pmatrix}$$

10

5

Taking the derivative of Equation XVI with respect to the complex conjugate of  $\mathbf{L}_A$  and setting it equal to zero results in the following Equation XVIII:

### **Equation XVIII**

$$\frac{\partial J}{\partial \overline{\mathbf{L}}_{A}} = \underbrace{\sum_{i} \overline{\widehat{\mathbf{F}}_{i}} \widehat{\mathbf{F}}_{i}}_{\widehat{\mathbf{A}}} \mathbf{L}_{A} + \underbrace{\sum_{i} \overline{\widehat{\mathbf{F}}_{i}} \widehat{\mathbf{F}}_{i} \widehat{\mathbf{W}}_{i}}_{\widehat{\mathbf{B}}} \mathbf{L}_{B} - \underbrace{\sum_{i} \overline{\widehat{\mathbf{F}}_{i}} \mathbf{H}_{i}}_{\widehat{\mathbf{C}}} = \mathbf{0}$$

15

Taking the derivative of Equation XVI with respect to the complex conjugate of  $\mathbf{L}_B$  and setting it equal to zero results in the following Equation XIX:

### **Equation XIX**

$$\frac{\partial J}{\partial \overline{\mathbf{L}}_{B}} = \underbrace{\sum_{i} \overline{\hat{\mathbf{W}}_{i}} \overline{\hat{\mathbf{F}}_{i}} \hat{\mathbf{F}}_{i}}_{\widetilde{\mathbf{B}}} \mathbf{L}_{A} + \underbrace{\sum_{i} \overline{\hat{\mathbf{F}}_{i}} \widehat{\mathbf{F}}_{i}}_{\widetilde{\mathbf{A}}} \mathbf{L}_{B} - \underbrace{\sum_{i} \hat{\mathbf{W}}_{i} \overline{\hat{\mathbf{F}}_{i}} \mathbf{H}_{i}}_{\mathbf{D}} = \mathbf{0}$$

20

The horizontal bar over the letters in Equations XVIII and XIX indicates that those letters represent a complex conjugate (i.e.,  $\bar{\mathbf{A}}$  represents the complex conjugate of  $\mathbf{A}$ ).

Solving Equations XVIII and XIX for  $L_A$  and  $L_B$  results in the following 5 Equations XX and XXI

## **Equation XX**

$$\mathbf{L}_{B} = \left(\overline{\widehat{\mathbf{B}}}\widehat{\mathbf{A}}^{-1}\widehat{\mathbf{B}}\right)^{-1} \left(\mathbf{D} - \widehat{\mathbf{A}}^{-1}\mathbf{C}\right)$$

### **Equation XXI**

$$\mathbf{L}_{A} = \widehat{\mathbf{A}}^{-1} \left( \mathbf{C} - \widehat{\mathbf{B}} \mathbf{L}_{B} \right)$$

10 Equations XX and XXI may be implemented in the frequency domain using pseudo-inverse filtering. In one embodiment, sub-frame generation unit 36 is configured to generate sub-frames 30 based on Equations XX and XXI.

## VIII. Adaptive Multi-Pass

An adaptive multi-pass algorithm for generating sub-frames 30 according to one embodiment uses past errors to update estimates for the sub-frame data, and provides fast convergence and low memory requirements. The adaptive multi-pass solution according to one embodiment is described in the context of the system 600 shown in Figure 9. The system 600 shown in Figure 9 can be represented mathematically in an error cost function by the following Equation XXII:

### **Equation XXII**

$$J^{(n)}(\mathbf{n}) = \left| e^{(n)}(\mathbf{n}) \right|^2 = \left( \sum_{\mathbf{k}} l_Q^{(n)}(\mathbf{k}) f(\mathbf{n} - \mathbf{k}) - h(\mathbf{n}) \right)^2$$
where:

n = index identifying the current iteration;  $J^{(n)}(\mathbf{n}) = \text{error cost function at iteration } n;$   $e^{(n)}(\mathbf{n}) = \text{square root of the error cost function,}$   $J^{(n)}(\mathbf{n});$ 

15

20

**n** and **k** = indices for identifying high resolution pixel locations in images 604 and 610;  $l_O^{(n)}(\mathbf{k}) = \text{image data from upsampled image 604 at}$ 

location k;

 $f(\mathbf{n} - \mathbf{k})$  = filter coefficient of the interpolating filter at a position  $\mathbf{n} - \mathbf{k}$ ; and  $h(\mathbf{n})$  = image data for desired high resolution

image 28 at location n.

As can be seen from Equation XXII, rather than minimizing a global spatial domain error by summing over the entire high resolution image as shown in Equation IX above, a local spatial domain error, which is a function of **n**, is being minimized.

A least mean squares (LMS) algorithm is used in one embodiment to determine the update, which is represented in the following Equation XXIII:

## 15 <u>Equation XXIII</u>

5

10

$$l_{Q}^{(n+1)}(\mathbf{t}) = l_{Q}^{(n)}(\mathbf{t}) + \alpha \frac{\partial J^{(n)}(\mathbf{n})}{\partial l_{Q}^{(n)}(\mathbf{t})}, \quad \mathbf{t} \in \Theta$$

where:

 $\Theta$  = the set of quincunx lattice points (i.e., the dark pixels in upsampled image 604 in Figure 9); and  $\alpha$  = sharpening factor.

Taking the derivative of Equation XXII provides the value for the derivative in Equation XXIII, which is given in the following Equation XXIV:

## **Equation XXIV**

$$\frac{\partial J^{(n)}(\mathbf{n})}{\partial l_Q^{(n)}(\mathbf{t})} = 2 \left( \sum_{\mathbf{k}} l_Q^{(n)}(\mathbf{k}) f(\mathbf{n} - \mathbf{k}) - h(\mathbf{n}) \right) f(\mathbf{n} - \mathbf{t})$$

In one embodiment, a block-LMS algorithm using the average gradient over a "region of influence" is used to perform the update, as represented by the following Equation XXV:

## Equation XXV

5

10

15

20

25

$$l_{Q}^{(n+1)}(\mathbf{t}) = l_{Q}^{(n)}(\mathbf{t}) + \alpha \sum_{\mathbf{n} \in \Omega} \frac{\partial J^{(n)}(\mathbf{n})}{\partial l_{Q}^{(n)}(\mathbf{t})}$$

where:

### $\Omega$ = region of influence

Figure 14 is a diagram illustrating regions of influence ( $\Omega$ ) 1106 and 1108 for pixels in an upsampled image 1100 according to one embodiment of the present invention. Pixel 1102 of image 1100 corresponds to a pixel for a first sub-frame, and pixel 1104 of image 1100 corresponds to a pixel for a second sub-frame. Region 1106, which includes a 2x2 array of pixels with pixel 1102 in the upper left corner of the 2x2 array, is the region of influence for pixel 1102. Similarly, region 1108, which includes a 2x2 array of pixels with pixel 1104 in the upper left corner of the 2x2 array, is the region of influence for pixel 1104.

Figure 15 is a diagram illustrating the generation of an initial simulated high resolution image 1208 based on an adaptive multi-pass algorithm according to one embodiment of the present invention. An initial set of low resolution subframes 30K-1 and 30L-1 are generated based on an original high resolution image 28. In the illustrated embodiment, the initial set of sub-frames 30K-1 and 30L-1 are generated using an embodiment of the nearest neighbor algorithm described above with reference to Figure 5. The sub-frames 30K-1 and 30L-1 are upsampled to generate upsampled image 1202. The upsampled image 1202 is convolved with an interpolating filter 1204, thereby generating a blocked image, which is then multiplied by a factor of 0.5 to generate simulated high resolution image 1208. In the illustrated embodiment, the interpolating filter 1204 is a 2x2 filter with filter coefficients of "1", and with the center of the convolution being the upper left position in the 2x2 matrix. The lower right pixel 1206 of the interpolating filter 1204 is positioned over each pixel in image 1202 to determine the blocked value for that pixel position. As shown in Figure 15, the lower right pixel 1206 of the interpolating filter 1204 is positioned over the pixel in the third row and fourth column of image 1202, which has a value of "0". The blocked value for that pixel position is determined by multiplying the

filter coefficients by the pixel values within the window of the filter 1204, and adding the results. Out-of-frame values are considered to be "0". For the illustrated embodiment, the blocked value for the pixel in the third row and fourth column of image 1202 is given by the following Equation XXVI

### Equation XXVI

5

10

15

20

25

30

$$(1 \times 0) + (1 \times 5) + (1 \times 5) + (1 \times 0) = 10$$

The value in Equation XXVI is then multiplied by the factor 0.5, and the result (i.e., 5) is the pixel value for the pixel 1210 in the third row and the fourth column of the initial simulated high resolution image 1208.

After the initial simulated high resolution image 1208 is generated, correction data is generated. Figure 16 is a diagram illustrating the generation of correction data based on the adaptive multi-pass algorithm according to one embodiment of the present invention. As shown in Figure 16, the initial simulated high resolution image 1208 is subtracted from the original high resolution image 28 to generate an error image 1302. Correction sub-frames 1312 and 1314 are generated by averaging 2x2 blocks of pixels in error image 1302. For example, the pixel 1308 in the first column and first row of error image 1302 has a region of influence 1304. The pixel values within the region of influence 1304 are averaged to generate a first correction value (i.e., 0.75). The first correction value is used for the pixel in the first column and the first row of correction sub-frame 1312. Similarly, the pixel 1310 in the second column and second row of error image 1302 has a region of influence 1306. The pixel values within the region of influence 1306 are averaged to generate a second correction value (i.e., 0.75). The second correction value is used for the pixel in the first column and the first row of correction sub-frame 1314.

The correction value in the first row and second column of correction sub-frame 1312 (i.e., 1.38) is generated by essentially sliding the illustrated region of influence box 1304 two columns to the right and averaging those four pixels within the box 1304. The correction value in the second row and first column of correction sub-frame 1312 (i.e., 0.50) is generated by essentially sliding the illustrated region of influence box 1304 two rows down and averaging those four pixels within the box 1304. The correction value in the

second row and second column of correction sub-frame 1312 (i.e., 0.75) is generated by essentially sliding the illustrated region of influence box 1304 two columns to the right and two rows down and averaging those four pixels within the box 1304.

5

10

15

20

25

30

The correction value in the first row and second column of correction sub-frame 1314 (i.e., 0.00) is generated by essentially sliding the illustrated region of influence box 1306 two columns to the right and averaging those pixels within the box 1306. Out-of-frame values are considered to be "0". The correction value in the second row and first column of correction sub-frame 1314 (i.e., 0.38) is generated by essentially sliding the illustrated region of influence box 1306 two rows down and averaging those pixels within the box 1306. The correction value in the second row and second column of correction sub-frame 1314 (i.e., 0.00) is generated by essentially sliding the illustrated region of influence box 1306 two columns to the right and two rows down and averaging those four pixels within the box 1306.

The correction sub-frames 1312 and 1314 are used to generate updated sub-frames. Figure 17 is a diagram illustrating the generation of updated sub-frames 30K-2 and 30L-2 based on the adaptive multi-pass algorithm according to one embodiment of the present invention. As shown in Figure 17, the updated sub-frame 30K-2 is generated by multiplying the correction sub-frame 1312 by the sharpening factor,  $\alpha$ , and adding the initial sub-frame 30K-1. The updated sub-frame 30L-2 is generated by multiplying the correction sub-frame 1314 by the sharpening factor,  $\alpha$ , and adding the initial sub-frame 30L-1. In the illustrated embodiment, the sharpening factor,  $\alpha$ , is equal to 0.8.

In one embodiment, updated sub-frames 30K-2 and 30L-2 are used in the next iteration of the adaptive multi-pass algorithm to generate further updated sub-frames. Any desired number of iterations may be performed. After a number of iterations, the values for the sub-frames generated using the adaptive multi-pass algorithm converge to optimal values. In one embodiment, sub-frame generation unit 36 is configured to generate sub-frames 30 based on the adaptive multi-pass algorithm.

The embodiment of the adaptive multi-pass algorithm described above with reference to Figures 15-17 is for two-position processing. For four-position processing, Equation XXIV becomes the following Equation XXVII:

### **Equation XXVII**

5

10

15

20

$$\frac{\partial J^{(n)}(\mathbf{n})}{\partial l^{(n)}(\mathbf{t})} = 2 \left( \sum_{\mathbf{k}} l^{(n)}(\mathbf{k}) f(\mathbf{n} - \mathbf{k}) - h(\mathbf{n}) \right) f(\mathbf{n} - \mathbf{t})$$
where:

 $l^{(n)}$  = low resolution data for the four sub-frames 30;

And Equation XXIII becomes the following Equation XXVIII:

### Equation XXVIII

$$l^{(n+1)}(\mathbf{t}) = l^{(n)}(\mathbf{t}) + \alpha \frac{\partial J^{(n)}(\mathbf{n})}{\partial l^{(n)}(\mathbf{t})}$$

For four-position processing, there are four sub-frames, so the amount of low resolution data is the same as the amount of high resolution data. Each high resolution grid point contributes one error, and there is no need to average gradient update as represented in Equation XXV above. Rather, the error at a given location directly gives the update.

As described above, in one embodiment, the adaptive multi-pass algorithm uses a least mean squares (LMS) technique to generate correction data. In another embodiment, the adaptive multi-pass algorithm uses a projection on a convex set (POCS) technique to generate correction data. The adaptive multi-pass solution based on the POCS technique according to one embodiment is described in the context of the system 600 shown in Figure 9. The system 600 shown in Figure 9 can be represented mathematically in an error cost function by the following Equation XXIX:

## **Equation XXIX**

5

10

15

$$|e(\mathbf{n})| = \left| \left( \sum_{\mathbf{k}} l_{Q}(\mathbf{k}) f(\mathbf{n} - \mathbf{k}) - h(\mathbf{n}) \right) \right|$$
  
where:

e(n) = error cost function;

n and k = indices identifying high resolution pixel
locations;

 $l_Q(\mathbf{k})$  = image data from upsampled image 604 at location  $\mathbf{k}$ ;

 $f(\mathbf{n} - \mathbf{k})$  = filter coefficient of the interpolating filter at a position  $\mathbf{n} - \mathbf{k}$ ; and

 $h(\mathbf{n})$  = image data for desired high resolution image 28 at location  $\mathbf{n}$ .

A constrained set for the POCS technique is defined by the following Equation XXX:

## **Equation XXX**

$$C(\mathbf{n}) = \left\{ l_{\mathcal{Q}}(n) : \left| \left( \sum_{\mathbf{k}} l_{\mathcal{Q}}(\mathbf{k}) f(\mathbf{n} - \mathbf{k}) - h(\mathbf{n}) \right) \right| \le \eta \right\}$$

where:  $C(\mathbf{n}) = \text{constrained}$ 

 $C(\mathbf{n})$  = constrained set that includes all sub-frame data from upsampled image 604 that is bounded by parameter,  $\eta$ ; and

 $\eta$  = error magnitude bound constraint.

The sub-frame pixel values for the current iteration are determined based on the following Equation XXXI:

## **Equation XXXI**

$$l_{Q}^{(n+1)}(\mathbf{t}) = \begin{cases} (1-\lambda) \ l_{Q}^{(n)}(\mathbf{t}) + \lambda \frac{e(\mathbf{n}^{*}) - \eta}{\left\|f\right\|^{2}} & e(\mathbf{n}^{*}) > \eta \qquad (\mathbf{t} \in \Theta) \\ (1-\lambda) \ l_{Q}^{(n)}(\mathbf{t}) + \lambda \frac{e(\mathbf{n}^{*}) + \eta}{\left\|f\right\|^{2}} & e(\mathbf{n}^{*}) < \eta \end{cases}$$

$$l_{Q}^{(n)}(\mathbf{t}) \quad e(\mathbf{n}^{*}) = \eta$$

where:

n = index identifying the current iteration;  $\lambda = \text{relaxation parameter; and}$ 

||f|| = norm of the coefficients of the interpolating filter.

The symbol,  $\mathbf{n}^*$ , in Equation XXXI represents the location in the region of influence,  $\Omega$ , where the error is a maximum, and is defined by the following Equation XXXII:

### **Equation XXXII**

5

10

15

20

25

$$\mathbf{n}^* = \operatorname{argmax} \{ \mathbf{n} \in \Omega : |e(\mathbf{n})| \}$$

Figure 18 is a diagram illustrating the generation of correction data based on the adaptive multi-pass algorithm using a POCS technique according to one embodiment of the present invention. In one embodiment, an initial simulated high resolution image 1208 is generated in the same manner as described above with reference to Figure 15, and the initial simulated high resolution image 1208 is subtracted from the original high resolution image 28 to generate an error image 1302. The Equation XXXI above is then used to generate updated subframes 30K-3 and 30L-3 from the data in error image 1302. For the illustrated embodiment, it is assumed that relaxation parameter,  $\lambda$ , in Equation XXXI is equal to 0.5, and the error magnitude bound constraint,  $\eta$ , is equal to 1.

With the POCS technique, rather than averaging the pixel values within the region of influence to determine a correction value as described above with reference to Figure 16, the maximum error, e(n\*), within the region of influence

is identified. An updated pixel value is then generated using the appropriate formula from Equation XXXI, which will depend on whether the maximum error,  $e(\mathbf{n}^*)$ , within the region of influence is greater than 1, less than 1, or equal to 1 (since  $\eta = 1$  for this example).

For example, the pixel in the first column and first row of error image 1302 has a region of influence 1304. The maximum error within this region of influence 1304 is 1 (i.e.,  $e(\mathbf{n}^*) = 1$ ). Referring to Equation XXXI, for the case where  $e(\mathbf{n}^*) = 1$ , the updated pixel value is equal to the previous value for this pixel. Referring to Figure 15, the previous value for the pixel in the first column and the first row of sub-frame 30K-1 was 2, so this pixel remains with a value of 2 in updated sub-frame 30K-3. The pixel in the second column and second row of error image 1302 has a region of influence 1306. The maximum error within this region of influence 1306 is 1.5 (i.e.,  $e(\mathbf{n}^*) = 1.5$ ). Referring to Equation XXXI, for the case where  $e(\mathbf{n}^*) > 1$ , the updated pixel value is equal to half the previous value for this pixel, plus half of the quantity  $(e(\mathbf{n}^*) - 1)$ , which is equal to 1.25. Referring to Figure 15, the previous value for the pixel in the first column and the first row of sub-frame 30L-1 was 2, so the updated value for this pixel is 1.25 in updated sub-frame 30L-3.

The region of influence boxes 1302 and 1304 are essentially moved around the error image 1302 in the same manner as described above with reference to Figure 16 to generate the remaining updated values in updated subframes 30K-3 and 30L-3 based on Equation XXXI.

## IX. <u>Diamond Grids and Diamond Pixels</u>

5

10

15

20

25

30

In one embodiment, analog image data 162 (Figure 1) is sampled by A/D converter 32 (Figure 1) on a rectangular grid. In the embodiments described above, the desired high resolution image 28 and the generated sub-frames 30 are made up of rectangular-shaped pixels arranged on rectangular grids. Figure 19A is a diagram illustrating rectangular-shaped (e.g., square) pixels 1360 on a rectangular grid 1362 according to one embodiment of the present invention. Four neighboring rectangular-shaped pixels 1360 are shown in Figure 19A. The centers 1364 of the pixels 1360 define a rectangular grid 1362. It will be

understood by persons of ordinary skill in the art that rectangular grid 1362, which is shown with four grid points 1364 and four pixels 1360, may include any desired number of grid points 1364 and pixels 1360.

5

10

15

20

25

30

Also shown in Figure 19A is a pair of orthogonal axes 1366 and 1368. X-axis 1368 represents a horizontal dimension, and Y-axis 1366 represents a vertical dimension. A row of pixels 1360 on rectangular grid 1362 is defined by drawing a line through the centers of pixels 1360 parallel to the horizontal dimension represented by X-axis 1368. A column of pixels 1360 on rectangular grid 1362 is defined by drawing a line through the centers of pixels 1360 parallel to the vertical dimension represented by Y-axis 1366. The rectangular grid 1362 shown in Figure 19A includes two rows and two columns of pixels 1360.

When displayed, each row of pixels 1360 on rectangular grid 1362 is parallel to the horizontal dimension represented by X-axis 1368, and each column of pixels 1360 on rectangular grid 1362 is parallel to the vertical dimension represented by Y-axis 1366. Also, any two adjacent pixels 1360 that are in the same row will be in adjacent columns, and any two adjacent pixels 1360 that are in the same column will be in adjacent rows.

In another embodiment of the present invention, analog image data 162 is sampled by A/D converter 32 on a diamond grid. In this embodiment, the desired high resolution image 28 and the generated sub-frames 30 are made up of diamond-shaped pixels arranged on diamond grids. Figure 19B is a diagram illustrating diamond-shaped pixels 1370 on a diamond grid 1372 according to one embodiment of the present invention. Four neighboring diamond-shaped pixels 1370 are shown in Figure 19B. The centers 1374 of the pixels 1370 define a diamond grid 1372. Diamond grid 1372 is also referred to as a quincunx grid. It will be understood by persons of ordinary skill in the art that diamond grid 1372, which is shown with four grid points 1374 and four pixels 1370, may include any desired number of grid points 1374 and pixels 1370.

A row of pixels 1370 on diamond grid 1372 is defined by drawing a line through the centers of pixels 1370 parallel to the horizontal dimension represented by X-axis 1368. A column of pixels 1370 on diamond grid 1372 is defined by drawing a line through the centers of pixels 1370 parallel to the

vertical dimension represented by Y-axis 1366. The diamond grid 1372 shown in Figure 19B includes three rows and three columns of pixels 1370.

When displayed, each row of pixels 1370 on diamond grid 1372 is parallel to the horizontal dimension represented by X-axis 1368, and each column of pixels 1370 on diamond grid 1372 is parallel to the vertical dimension represented by Y-axis 1366. However, unlike rectangular grid 1362, when pixels 1370 on diamond grid 1372 are displayed, any two adjacent pixels 1370 that are in the same row will not be in adjacent columns, and any two adjacent pixels 1370 that are in the same column will not be in adjacent rows. The pixels 1370 in adjacent rows are offset from one another in the horizontal dimension represented by X-axis 1368, rather than being aligned with one another like pixels 1360 on rectangular grid 1362.

5

10

15

20

25

30

In one form of the invention, sub-frame generation unit 36 (Figure 1) is configured to generate sub-frames 30 having rectangular grids of rectangular-shaped pixels, and display device 26 (Figure 1) is a low resolution rectangular display that is configured to display these generated rectangular sub-frames 30. In another form of the invention, sub-frame generation unit 36 is configured to generate sub-frames 30 having diamond grids of diamond-shaped pixels, and display device 26 is a low resolution quincunx display that is configured to display these generated diamond sub-frames 30. Diamond grids have some advantages over rectangular grids, including: (1) The sub-frame pixels line up in rows and columns so it is possible to compute a resolution specification; and (2) signals sampled on diamond grids alias first along the diagonal frequencies where humans are less visually sensitive, rather than at the vertical and horizontal frequencies. The display of sub-frames 30 having diamond-shaped pixels arranged on diamond grids is described in further detail below with reference to Figures 20 and 21.

Figure 20 is a diagram illustrating the display of two sub-frames 30M and 30N with diamond-shaped pixels and a horizontal offset between sub-frames according to one embodiment of the present invention. Sub-frame 30M includes nine low resolution diamond-shaped pixels 1404M (shown in Figure 20 with stippled shading) organized in three rows and three columns, and sub-frame 30N

includes nine low resolution diamond-shaped pixels 1404N (shown in Figure 20 with horizontal line shading) organized in three rows and three columns. The pixels for sub-frames 30M and 30N are each arranged on a low resolution diamond grid.

5

10

15

20

25

30

Sub-frame 30N is shifted horizontally to the right with respect to sub-frame 30M by a sub-pixel amount (e.g., one half pixel). When sub-frames 30M and 30N are displayed in relatively quick succession using two-position processing, the displayed image appears to the human visual system to have a higher resolution than either of the individual sub-frames 30M and 30N. The displayed image appears to have high resolution pixels 1406. The high resolution pixels 1406 are also diamond-shaped, and are positioned on a high resolution diamond grid 1402. The display of two temporally and spatially shifted sub-frames with diamond-shaped pixels on diamond grids is referred to herein as diamond two-position processing. If the diamond grids for sub-frames 30M and 30N are rotated forty-five degrees, the diamond two-position processing shown in Figure 20 is the same as two-position processing on a rectangular grid using a horizontal and vertical spatial offset (i.e., a diagonal shift) between sub-frames, such as shown in Figures 2A-2C.

Figure 21 is a diagram illustrating the display of two sub-frames 30P and 30Q with diamond-shaped pixels and a diagonal offset between sub-frames according to one embodiment of the present invention. Sub-frame 30P includes nine low resolution diamond-shaped pixels 1504P (shown in Figure 21 with horizontal stippled shading) organized in three rows and three columns, and sub-frame 30Q includes nine low resolution diamond-shaped pixels 1504Q (shown in Figure 21 with horizontal line shading) organized in three rows and three columns. The pixels for sub-frames 30P and 30Q are each arranged on a low resolution diamond grid.

Sub-frame 30Q is shifted in a diagonal direction (e.g., down and to the right) by a sub-pixel amount (e.g., one half pixel) with respect to sub-frame 30P. Four position processing is accomplished by providing two additional sub-frames 30, which would appear the same as shown in Figure 21 for sub-frames 30P and 30Q, but shifted in a diagonal direction (e.g., up and to the right) by a

sub-pixel amount (e.g., one half pixel) with respect to sub-frames 30P and 30Q, as indicated by hidden lines 1508. When four sub-frames 30 are displayed in relatively quick succession using four-position processing, the displayed image appears to the human visual system to have a higher resolution than the individual sub-frames 30. The displayed image appears to have high resolution pixels 1506. The high resolution pixels 1506 are also diamond-shaped, and are positioned on a high resolution diamond grid. The display of four temporally and spatially shifted sub-frames with diamond-shaped pixels on diamond grids is referred to herein as diamond four-position processing. If the diamond grids for the four sub-frames 30 are rotated forty-five degrees, the diamond four-position processing shown in Figure 21 is the same as four-position processing on a rectangular grid, such as shown in Figures 4A-4E.

5

10

15

20

25

30

As described above, the spatial domain, frequency domain, and adaptive multi-pass algorithms, according to one form of the invention, are used to generate sub-frames 30 based on minimization of an error metric between a desired high resolution image 28 (Figure 11) and a simulated high resolution image. In the above-described embodiments of these algorithms, it was assumed that the high resolution image 28 and the sub-frames 30 were made up of rectangular-shaped pixels on rectangular grids. In another embodiment, high resolution image 28 and sub-frames 30 are made up of diamond-shaped pixels on diamond grids.

In one embodiment, the problem of generating optimal sub-frames 30 with diamond-shaped pixels on a diamond grid is solved by transforming the problem to an equivalent one on a rectangular grid with square pixels. The above-described spatial domain algorithm, frequency domain algorithm, or adaptive multi-pass algorithm is then used to generate optimal sub-frames 30 for the rectangular grid. The sub-frames 30 are then transformed back to a diamond grid. One embodiment of a method performed by sub-frame generation unit 36 (Figure 1) for generating optimal sub-frames 30 with diamond pixels on a diamond grid is described in further detail below with reference to Figures 22 and 23.

Figure 22 is a diagram illustrating a rectangular-shaped high resolution image 1600 on a rectangular grid 1606 generated from a diamond-sampled high resolution image 1602 according to one embodiment of the present invention. Diamond-sampled high resolution image 1602 is originally sampled by A/D converter 32 (Figure 1) on a diamond grid. Diamond-sampled high resolution image 1602 is then rotated by forty-five degrees by sub-frame generation unit 36 to convert the image 1602 to a rectangular grid 1606. In one embodiment, the rotation is accomplished by a coordinate transformation that converts each horizontal row of pixels to a diagonal line of pixels. Diamond-sampled high resolution image 1602 includes high resolution pixels 1604A (shown in Figure 22 with stippled shading). After rotation, image 1602 is then padded with pixels 1604B having a value of zero to produce the rectangular-shaped image 1600.

5

10

15

20

25

30

In one embodiment, after rectangular-shaped high resolution image 1600 is generated by sub-frame generation unit 36, optimal sub-frames on a rectangular grid are generated as described above, using the spatial domain algorithm, frequency domain algorithm, or adaptive multi-pass algorithm. Rectangular-shaped high resolution image 1600 represents the desired high resolution image 28 (Figure 11) in these algorithms.

Image 1600 includes several pixels 1604B having a zero value, which are padded around the diamond-sampled high resolution image 1602. In one embodiment, the sub-frame data corresponding to these pixels 1604B is discarded, and only the sub-frame data corresponding to the diamond-sampled high resolution image 1602 is used for display by display device 26. In another embodiment, only sub-frame data corresponding to the diamond-sampled high resolution image 1602 is generated by sub-frame generation unit 36, and sub-frame data corresponding to pixels 1604B is not generated. In the example image 1600 shown in Figure 22, low resolution sub-frame pixels that are used for display are shown overlaid on the high resolution pixels 1604A. The low resolution sub-frame pixels include nine sub-frame pixels 1610A (shown in Figure 22 with diagonal line shading) for a first sub-frame, and nine sub-frame pixels 1610B (shown in Figure 22 with diagonal line shading perpendicular to the shading for pixels 1610A) for a second sub-frame. Each low resolution pixel

1610A or 1610B covers a 2x2 block of high resolution pixels. The pixels 1604B shown in Figure 22 that include at least one pixel border defined by a hidden line 1608 are not part of the diamond-sampled high resolution image 1602, but are part of one of the sub-frame pixels 1610A or 1610B.

5

10

15

20

25

30

In one embodiment, after the optimal sub-frames on a rectangular grid are generated by sub-frame generation unit 36, the generated sub-frames are transformed to a diamond grid by unit 36 for display by display device 26. Figure 23 is a diagram illustrating the transformation of low resolution subframes 30R-1 and 30S-1 on a rectangular grid to low-resolution sub-frames 30R-2 and 30S-2 on a diamond grid according to one embodiment of the present invention. Sub-frame 30R-1 includes nine rectangular-shaped low resolution pixels 1704R-1. Sub-frame 30S-1 includes nine rectangular-shaped low resolution pixels 1704S-1. In one form of the invention, sub-frames 30R-1 and 30S-1 are transformed to a diamond grid by rotating the sub-frames by forty-five degrees. Sub-frames 30R-2 and 30S-2 represent sub-frames 30R-1 and 30S-1, respectively, after rotation. Sub-frame 30R-2 includes nine diamond-shaped low resolution pixels 1704R-2. Sub-frame 30S-2 includes nine diamond-shaped low resolution pixels 1704S-2. In one embodiment, the rotation is accomplished by a coordinate transformation that converts each diagonal line of pixels 1704R-1 or 1704S-1 in sub-frame 30R-1 or 30S-1 to a horizontal line of pixels 1704R-2 or 1704S-2. In one embodiment, the generated sub-frames 30R-2 and 30S-2 are displayed by display device 26 using diamond two-position processing to give the appearance of a higher resolution image on a diamond grid.

In another embodiment of the present invention, sub-frames 30 having diamond shaped pixels on diamond grids are generated by sub-frame generation unit 36 based on a diamond sampled high resolution image using the nearest neighbor algorithm or the bilinear algorithm, which are described above with reference to Figures 5 and 6. In one form of the invention, transformations between diamond grids and rectangular grids are performed as described, such that the nearest neighbor algorithm or bilinear algorithm are applied on a rectangular grid. In another form of the invention, such transformations are not performed, and the nearest neighbor algorithm, bilinear algorithm, or a variation

of these algorithms, is applied by sub-frame generation unit 36 to generate sub-frames 30 on a diamond grid directly from a diamond sampled high resolution image.
